

# Agilent Signal Generator Spectral Purity

Application Note 388

Why is spectral purity important?  
Why does this test keep failing?  
Where is the noise coming from?  
Is it my design or the signal generator?

**Agilent Technologies**

Innovating the HP Way

## What is spectral purity?

Spectral purity is the inherent stability of a signal. Does it change in frequency? Stabilities can either be short or long term. Drift or long-term stability is usually defined over a period of time greater than a second. Does the signal drift off frequency in minutes, hours, days, or months? Current signal generator technology generally offers good long-term stability.

The greater concern is for short-term stability or changes in frequency in less than one second. These fluctuations come from non-deterministic signals; noise, shot noise and 1/f flicker noise that modulates the carrier. These affect both phase and amplitude.

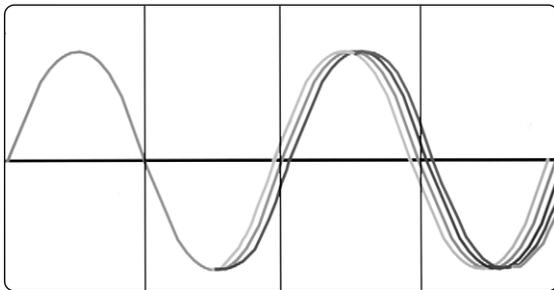

Figure 1. Oscilloscope display of short-term frequency fluctuations

## What are the components?

### Single-sideband phase noise

There are many ways to define spectral purity. The most common and meaningful method of specifying short-term stability is a plot of the signal generator's single-sideband (SSB) phase noise in a 1 Hz bandwidth versus the offset from the carrier. This is illustrated in figure 2. The SSB phase noise is expressed in dB relative to the carrier (dBc). A 1 Hz bandwidth is used since the noise in other bandwidths can then be easily calculated for comparison. This plot is a graphical representation of the phase noise distribution on one side of the carrier.

### Spurious

Non-random or deterministic signals are created from mixing and dividing signals to get the carrier frequency. These signals may be harmonically related to the carrier and are called subharmonics. The non-harmonic spectral line is called spurious. It is specified in amplitude in relation to the carrier (dBc).

### Residual FM

Residual FM is the undesired angular modulation or FM inherent in a signal generator with all the modulation turned off. It includes the effects of both spurious and phase noise. It is the integral or area under the SSB curve with limits set by the post-detection bandwidth. 300 Hz to 3 kHz and 20 Hz to 15 kHz are common bandwidths.

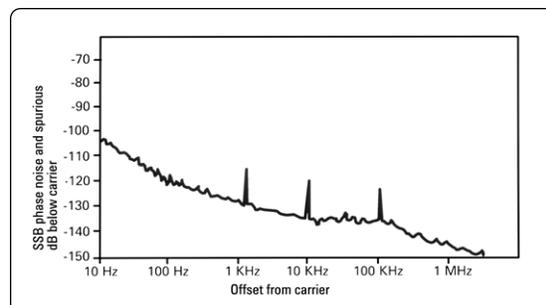

Figure 2. Signal generator SSB phase noise and spurious

# Why is spectral purity important?

## Mobile radio – narrower channel spacings

As available spectrum becomes more and more scarce, radio channel spacings will decrease. This puts a tighter constraint on receiver designers to design more selective receivers. To test receiver selectivity, a signal generator must have good spectral purity. If not, you will be testing your generator and not your receiver.

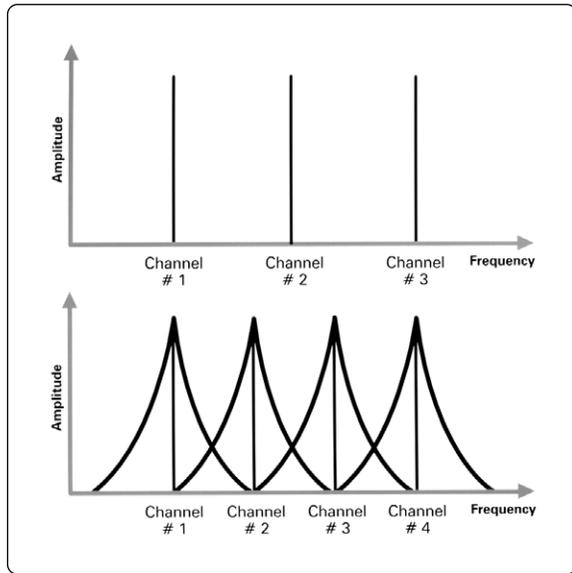

Figure 3. Smaller channel spacings mean greater need for spectral purity

## The measurement: adjacent channel selectivity

One common measurement for testing receiver rejection of unwanted signals is adjacent channel selectivity. Figure 4 shows a receiver IF (intermediate frequency) pass-band with a signal in-channel at a set sensitivity level. A second signal generator is set one channel spacing away. Its amplitude is increased until the signal punches through the pass-band and distorts the in-channel audio signal a set amount. The difference of the two signal levels is called adjacent channel selectivity.

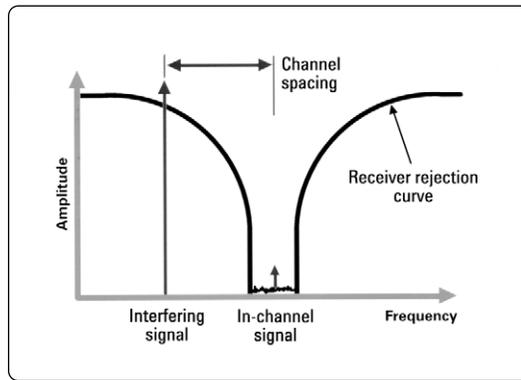

Figure 4. Receiver IF pass-band with in-channel signal present

# How signal generator spectral purity affects measurements

## Phase noise

Figure 5 shows what happens if the signal generator has high levels of phase noise. The phase noise spills into the pass-band, creating higher distortion on the desired signal. The receiver looks worse than it is.

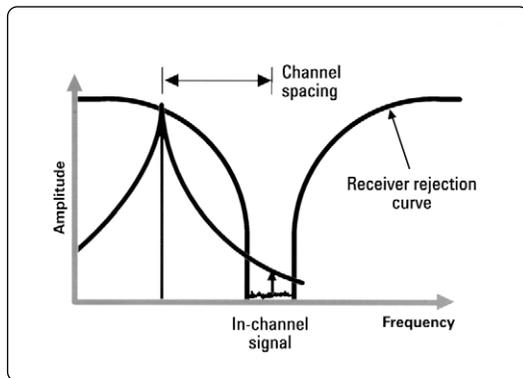

Figure 5. Out-of-channel phase noise causes in-channel distortion

## Spurious

Spurious causes much the same problem as phase noise. If a spurious signal shows up in the channel spacing of the radio, you will be measuring the difference in amplitudes of the spurious signal and the out-of-channel signal generator.

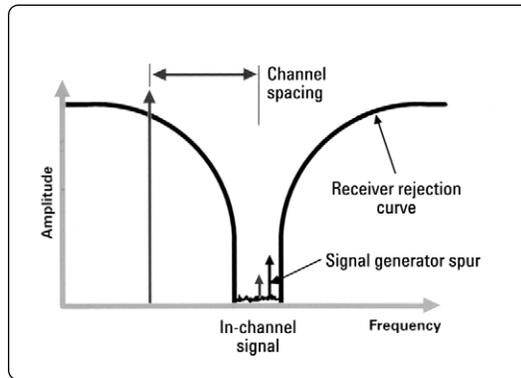

Figure 6. In-channel spurious signals makes a receiver look worse than it is

## Another measurement for receivers

### Hum and noise

Hum and noise measurement determines a receiver's signal-to-noise ratio. It is a ratio of a strong RF signal with audio present to the same signal with no audio present. It is measured in dB.

### Signal generator residual FM

High noise of a signal generator is directly added to the receiver noise. This gives a lower hum and noise ratio. Again it makes the receiver look worse than it is.

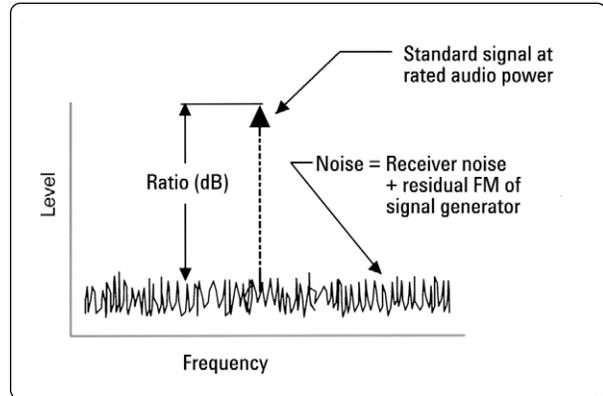

Figure 7. Signal generator residual FM adds to receiver noise levels

# Why is spectral purity important for local oscillator substitution?

## Signal generator as a local oscillator

Spectral purity is needed on signal generators used as local oscillators. Let's look at two signals,  $f_1$  and  $f_2$ , in figure 8. These signals will be mixed with a local oscillator signal (figure 9) down to an intermediate frequency (IF) where highly selective IF filters can separate one of the signals for amplification, detection, and baseband processing. If the desired signal is the larger signal, there should be no difficulty recovering it.

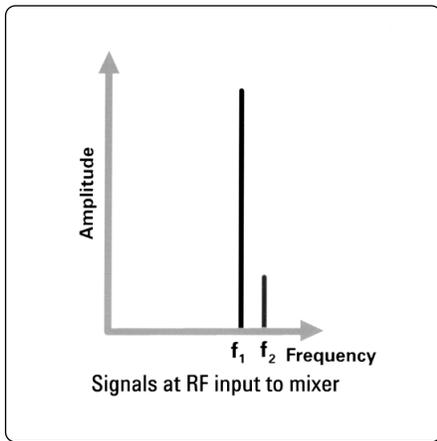

Figure 8. Two signals to be down-converted with a local oscillator

## How signal generator spectral purity affects the measurement

### Phase noise

Any phase noise on the local oscillator signal is translated directly to the mixer products. If the desired signal is the smaller of the two mixed signals, the translated noise in the mixer output may completely mask the smaller signal.

Even though the receiver's IF filtering may be sufficient to remove the larger signal's mixing product, the smaller signal's mixing product is no longer recoverable. This effect worsens in receivers with high selectivity and wide dynamic range.

### Spurious

Spurious signals on a local oscillator will cause the desired output to vary in phase at the IF frequency. This is a possible source of intermodulation products.

### Residual FM

Residual FM or noise is directly added to the signals at the output of the mixer. This effect becomes more critical, the closer the signals are together.

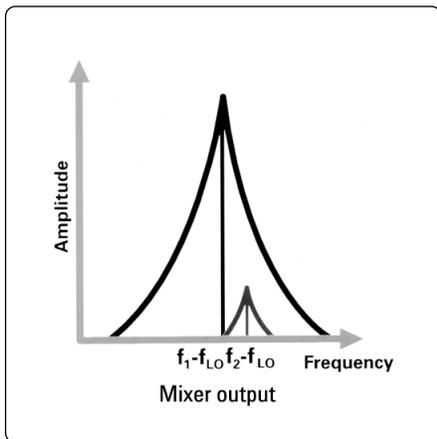

Figure 10. Phase noise masks the lower-amplitude signal

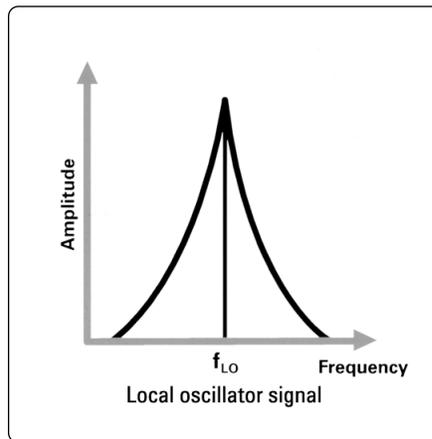

Figure 9. Local oscillator with phase noise

# Spectral purity in local oscillator applications

## Testing radar

Radar systems continue to demand greater resolution of targets. This puts higher requirements for spectral purity on local oscillators/signal generators.

For example, airborne and over-the-horizon radars want to detect slow moving surface vehicles. They must detect very low level return signals, which have very small doppler shifts.

Figure 11 shows signals from the ground return and the smaller doppler-shifted return from the moving vehicle. It also shows the effect of phase noise on the return signal. It will mask out the return or smaller signal.

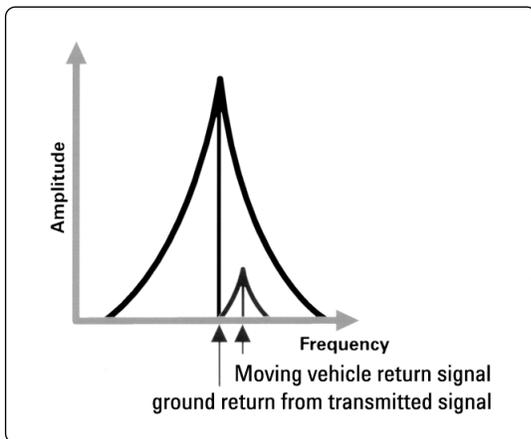

Figure 11. The effect of phase noise on radar

## Making phase noise measurements of your devices

Another application where spectral purity is critical for a local oscillator (LO) is in phase noise measurements. One of the most sensitive measurement techniques is the two-source phase detector technique. A signal is down converted with a LO to 0 Hz and examined on a low-frequency spectrum analyzer. This method is used by the Agilent 3048A phase noise measurement system. This proven technique requires a local oscillator with as good, or better, phase noise than the device under test. It is directly added into the measurement.

**Agilent Technologies' Test and Measurement Support, Services, and Assistance**

Agilent Technologies aims to maximize the value you receive, while minimizing your risk and problems. We strive to ensure that you get the test and measurement capabilities you paid for and obtain the support you need. Our extensive support resources and services can help you choose the right Agilent products for your applications and apply them successfully. Every instrument and system we sell has a global warranty. Support is available for at least five years beyond the production life of the product. Two concepts underlie Agilent's overall support policy: "Our Promise" and "Your Advantage."

**Our Promise**

Our Promise means your Agilent test and measurement equipment will meet its advertised performance and functionality. When you are choosing new equipment, we will help you with product information, including realistic performance specifications and practical recommendations from experienced test engineers. When you use Agilent equipment, we can verify that it works properly, help with product operation, and provide basic measurement assistance for the use of specified capabilities, at no extra cost upon request. Many self-help tools are available.

**Your Advantage**

Your Advantage means that Agilent offers a wide range of additional expert test and measurement services, which you can purchase according to your unique technical and business needs. Solve problems efficiently and gain a competitive edge by contracting with us for calibration, extra-cost upgrades, out-of-warranty repairs, and on-site education and training, as well as design, system integration, project management, and other professional engineering services. Experienced Agilent engineers and technicians worldwide can help you maximize your productivity, optimize the return on investment of your Agilent instruments and systems, and obtain dependable measurement accuracy for the life of those products.

**By internet, phone, or fax, get assistance with all your test & measurement needs**
